Communicated by the Director SAAO
Received 1976 September 13; in original form 1976 June 2

Summary. Spectra of 912 G - and K-type stars in six galactic directions $\left(l^{\mathrm{II}}=90^{\circ}, b^{\mathrm{II}}= \pm 20^{\circ} ; l^{\mathrm{II}}=180^{\circ}, b^{\mathrm{II}}= \pm 20^{\circ} ; l^{\mathrm{II}}=90^{\circ}, b^{\mathrm{II}}=+45^{\circ} ; b^{\mathrm{II}}=\right.$ $+90^{\circ}$ ) have been secured. The relevant space motions of the stars, subdivided into distance groups have been derived and these show no significant departures from the mean motion of nearby stars. The velocity dispersions, in general, indicate that these (mainly giant) stars are moderately old. The dispersion in $u$, however, is lower than that for nearby stars and the significance of this result is discussed.

## 1 Introduction

Some years ago when the Royal Greenwich Observatory (RGO) was conducting joint radial velocity programmes with the Helwan Observatory of the United Arab Republic, interest was expressed in the question whether the solar velocity relative to the nearby stars was the same as the velocity relative to stars some hundreds of parsecs distant and a number of velocities of K-type stars were measured to test this. In each case the spectral type of the star on the MK system was determined as well as the radial velocity, in order to determine its distance.

As the results from these studies were somewhat inconclusive, it was decided to supplement the data by conducting a similar series of observations, this time on $G$ stars using the 36 - and 98 -in reflector telescopes at the RGO.

## 2 Selection and observation

The $G$ and $K$ stars were selected from the Henry Draper catalogue such that they lay in six

[^0]Table 1. The selected areas.

| $l^{\text {II }}$ | $b^{\text {II }}$ | RA range <br> (h) | dec range | Area name |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |
| 90 | +45 | $15-17$ | $50-70$ | A |
| 90 | +20 | $18-20$ | $55-65$ | B |
| 90 | -20 | $21-00$ | $28-38$ | C |
|  | +90 | $12-14$ | $23-33$ | D |
| 180 | +20 | $06-08$ | $33-45$ | E |
| 180 | -20 | $03-05$ | $12-22$ | F |

areas corresponding to six directions of galactic longitude and latitude. The areas are defined in Table 1.

Details of the spectroscopic observations and reduction to radial velocity and spectral types are shortly to be published in Royal Observatory Annals so that only a brief account of the observations will be given here. Table 2 lists the proportion of stars observed on each telescope together with the relevant spectrographic dispersions used and the typical standard error in radial velocity.

Table 2. Summary of observations.

| No. stars | Sp. type | Telescope <br> $($ in $)$ | Dispersion <br> $(\mathrm{A} / \mathrm{mm})$ | Mean s.e. <br> $(\mathrm{km} / \mathrm{s})$ |
| :---: | :--- | :--- | :---: | :---: |
| 538 | K | 74 (Helwan) | 66 | 5 |
| 262 | G | 98 (RGO) | 60 | 4 |
| 59 | G | 98 (RGO) | 180 | 10 |
| 53 | G | 36 (RGO) | 80 | 6 |

The spectral types were determined by comparing the spectra with those of a range of MK standard stars (at different densities of exposure) taken with the same equipment.

Most of the stars were observed at least twice and it became clear that before a final solution could be made, some of the stars would have to be removed from the initial sample. Those rejected were:
(a) stars with apparently variable velocity ( 10 per cent of the total),
(b) stars which exhibited peculiar spectra, composite etc. (3 per cent),
(c) stars whose spectral type did not lie in the range $\mathrm{F} 8-\mathrm{K} 3$ ( 5 per cent),
(d) stars which were, or suspected to be, members of the Hyades group (4 per cent). (This concerned area F only.)
The identification of Hyades members made from the lists of van Bueren (1952) and Wayman, Symms \& Blackwell (1965) and a total of 33 probable and eight possible Hyades stars were excluded.

Finally, the sample was sorted into distance groups for each area (except A and D) as shown in Table 3. Also shown in this Table are the corresponding distance ranges above and below the galactic plane $(Z)$.

## 3 Reddening, magnitudes and spectral types

In order to examine the effect of velocity with distance for these stars we need to know the apparent and absolute magnitudes and the interstellar reddening. The apparent magnitudes

Table 3. The distance groups for each area.

| $m-M$ <br> range <br> (mag) | Distance range <br> $(\mathrm{pc})$ | $Z$ range <br> $(\mathrm{pc})$ | Group name |
| :--- | :--- | :--- | :--- |
| $0-5$ | $1-100$ | $1-50$ | 1 |
| $5-7$ | $100-250$ | $50-100$ | 2 |
| $7-8$ | $250-400$ | $100-200$ | 3 |
| $>8$ | $>400$ | $>200$ | 4 |

were taken entirely from the HD catalogue; however, as an independent check on these magnitudes and to some extent, the derived spectral types (which in turn leads to a value of the reddening) photoelectric ( $U B V$ ) photometry was obtained for a sample of the stars (in area C) using the 12 -in reflector at Sierra Nevada, Spain. Table 4 lists the derived spectral types, HD magnitudes, the Spanish magnitudes, the colours and the reddening determined from these types and the unreddened values according to FitzGerald (1970). If the derived types are reliable then, for this area, the reddening is negligible for all distance groups. An attempt to determine the reddening with distance in the remaining five areas from stars listed in the Bright star catalogue, Hoffleit (1964) showed that, in general, the reddening was small. As a result it has been treated as zero in the final solutions.

Table 4. Comparison of the Spanish and HD magnitudes.

| HD | Sp. type | $m$ <br> $(\mathrm{ptm})$ | $m$ <br> $(\mathrm{ptg})$ | $V$ | $B-V$ | $U-B$ | Date <br> $(1970)$ | $E(B-V)$ | Dist. <br> group |

| 1315 | G8 III | 7.9 | 8.7 | 7.57 | 0.95 | 0.67 | 26 Oct-2/3 Nov 0.00 | 3 |  |

It should be emphasized that in a statistical study of an adequately large sample of stars, such as this, the reddening, providing it is reasonably uniform, does not affect the general result. This is so since we are investigating the possible changes of velocity ratios with distance rather than the precise distances to which our mean values refer. It is also true that the apparent magnitudes need to be consistent rather than strictly accurate.

A comparison of the derived spectral types with those appearing in other lists namely Jaschek, Conde \& de Sierra (1964) and Kennedy \& Buscombe (1974) is made in Table 5. With a few exceptions the agreement is good. As the total sample is sufficiently large a few poorly determined types will not be of statistical importance.

## 4 The solutions

Following Woolley et al. (1965) a star's radial velocity may be resolved into three components of galactic motion and we can write
$\rho=u l_{3}+v m_{3}+w n_{3}+K$
where $\rho$ is the radial velocity.
$u, v, w$ are the orthogonal components of the stellar velocity,
$l_{3}, m_{3}, n_{3}$ are the appropriate direction cosines,
$K$ is the expansion term which previous analyses have shown can be ignored.
A least-squares solution for a group of stars well distributed about the sky gives mean values of the galactic motion ( $u_{0}, v_{0}, w_{0}$ ) for those stars. However, if for example we examine a group of stars in the direction of galactic rotation where values of $l_{3}$ and $n_{3}$ are near zero and $m_{3} \sim 1$, then an analysis of the velocities is a good measure of the $v_{0}$ component of velocity only if mean values of $u_{0}$ and $w_{0}$ from a more complete sample are fed into the equations.

In this case we have
$\rho^{1}=\rho-u_{0} l_{3}-w_{0} n_{3}=v m_{3}$
from which we get the normal equation
$\Sigma m_{3} \rho^{1}=v_{0} \Sigma m_{3}^{2}$.
Similarly $u_{0}$ and $w_{0}$ may be obtained from observations of stars away from the Galactic Centre and towards the North Galactic Pole.

In this way values of $u_{0}, v_{0}$ or $w_{0}$ were calculated for different distance groups of stars in the areas A-F of Table 1. Mean values of $u_{0}=-7.6 \mathrm{~km} / \mathrm{s}, v_{0}=-17.3 \mathrm{~km} / \mathrm{s}$ and $w_{0}=$ $-5.5 \mathrm{~km} / \mathrm{s}$ were adopted. These were derived from 800 nearby evolved G and K stars from Wilson's (1953) catalogue.

As the galactic longitudes lie near $90^{\circ}$ and $180^{\circ}$ the effect of neglecting a galactic rotation term amounts, at most, to $2 \mathrm{~km} / \mathrm{s}$ and has been ignored.

## 5 Results

The velocity solutions are given in Table 6 as follows:
Columns 1, 2: The area and distance groups as defined in Tables 1 and 3. The galactic longitude and latitude are given below the area name.

Columns 3, 4: The median distances from the Sun above and below the galactic plane ( $\bar{Z}=\bar{R} \sin b^{\mathrm{II}}+10 \mathrm{pc}$ ).

Columns 5, 6 : The number of stars in each distance group divided into dwarfs (class V ) and giants (classes II, III and IV).

Columns 7, 8, 9: The velocity solutions which consist of: the differences of the derived velocities from the mean motions (i.e. $-7.6-u,-17.3-v,-5.5-w$ ), the associated standard errors and velocity dispersions (where $\sigma=\sqrt{ } N \times$ standard error and $N$ is the number of stars). The dispersions for area A have components in both $v$ and $w$ and are referred to as $\sigma_{v} / \sigma_{w}$.

## 6 Discussion

The results of this investigation are embodied in Table 6 and show no departure from the mean motion of the nearby stars greater than can nearly be accounted for in terms of their standard errors, and no greater significance can be claimed for them. The velocity dispersions themselves indicate that the stars have an age not inconsistent with a moderately old (disc) population of stars, but the dispersions in $u$ show consistently low values (as set out in Tables 7 and 8 ) while the other two dispersions $\sigma_{v}$ and $\sigma_{w}$ are normal, that is to say, very similar to those shown by the nearby stars in general.

The results shown in Table 6 have a great deal of weight, in the sense of the number of stars contributing to them. A possible explanation for the lower values of $\sigma_{u}$ is that the sample examined in the survey in this paper consists predominantly of giant stars whereas the surveys of nearby stars shown in Table 7 are dominated by dwarfs, and for this reason Table 8 was drawn up which shows the nearby giants counted separately; with a reduction in $\sigma_{u}$ from $37 \mathrm{~km} / \mathrm{s}$ for 760 mixed stars to $34 \mathrm{~km} / \mathrm{s}$ for 103 nearby giants. This is still not as low as the $31 \mathrm{~km} / \mathrm{s}$ found from a larger number of giants in the regions surveyed in this paper, but the associated standard errors in $\sigma_{u}$ make this difference barely significant.

In Table 9 we compare the ratio of the velocity dispersions with other groups of stars of different ages.

The high value of $\sigma_{v} / \sigma_{u}$ found for giants is not unique as it has been found before, notably by Feast (1963) and Feast et al. (1972) in surveys of late-type variables. A puzzling feature of the giants is the lack of any great disturbance from the circular velocity, which the late-type variables do show. No doubt a solution to this peculiar problem in terms of the age of the giant stars concerned will be sought but the present authors do not offer one. The facts concerning the dispersions which have been brought to light appear to us, however, to merit further study.

## Acknowledgments

It is a pleasure to thank all those who have helped in the observation of the stars and the reduction of the data. In particular from the United Arab Republic: Dr K. Ali and A. Asaad and Mr F. Fahim; from RGO, Drs R. G. Bingham and B. L. Webster, Mrs M. Broadhurst, Miss J. Marris, Miss E. A. Epps, Mr A. J. Penny, Mr H. E. Davies and Ann Savage. Also thanks are due to the staff of the Computer Section of the Nautical Almanac Office at RGO for their assistance with the many computer runs. We thank also Dr M. W. Feast who has provided us with many constructive comments on the manuscript and to Dr S. V. M. Clube and Professor Lynden-Bell for a lively discussion. Miss Y. Z. R. Thomas typed the manuscript with speed and efficiency.
