### Abstract

Aspergillosis, which was first discovered in late 19th century, is a relatively rare disease in the sinuses. In recent years, a number of invasive aspergillosis infections of the maxillary sinus in immunocompromised patients, as well as the non-invasive form of the disease, have been reported. They were caused by the materials used in endodontic treatment, like gutta-percha, antrolith and by foreign bodies. This paper reports a case of aspergillosis in the maxillary sinus of an immunocompromised patient. It is associated with a root fragment after a much earlier tooth extraction.
